# THE OTHER CONSEQUENCES OF A PROBLEM-BASED MATHEMATICS CURRICULUM

DAVID CLARKE AND MARGARITA WALLBRIDGE

#### INTRODUCTION

Among the debates engaging the energies of the mathematics education community, one of the more energetic has concerned the role of problem solving in mathematics instruction. This debate has encompassed issues from what constitutes a problem to whether problem solving should be the medium or the message of the mathematics curriculum (for instance, Clarke and McDonough, 1989; Lawson, 1990; Owen & Sweller, 1989; Schoenfeld, 1985). Claims and counter-claims have been made regarding the advisability and the feasibility of basing a mathematics syllabus on non-routine mathematics tasks. Attempts to evaluate the success of such curricula have typically employed achievement tests to distinguish student outcomes. The authors of this study felt that a problem-based curriculum would be characterised more appropriately by the belief systems which the instructional program engendered in participating students than by the students' achievement on conventional mathematical tasks.

It is a student's belief systems that are likely to influence the student's subsequent participation in the study of mathematics, to structure their consequent learning of mathematics, and to guide and facilitate the application of mathematical skills to everyday contexts. If it could be demonstrated that student achievement on conventional mathematics tasks was enhanced by a problem-based program, and if student performance on non-routine problem-solving tasks was heightened by such a program, the ultimate value of the instruction would depend still on whether the student chooses to continue to study mathematics, develops a set of beliefs which supports and empowers further learning and sees any relevance in the skills acquired in class for situations encountered in the world beyond the classroom. Conventional instruction does little to address such concerns, and research has commonly ignored such outcomes.

## THE INSTRUCTIONAL PROGRAM

In 1989, the California Post-Secondary Education Commission (CPEC) released a request for proposals that would drastically revamp the Algebra I-Geometry-Algebra II sequence. The curriculum envisioned in the guidelines would set "problem solving, reasoning and communication as major goals; include such areas as statistics and discrete mathematics; and make important use of technology" (CPEC, 1989, p. 4). The IMP Curriculum Development Project obtained funding to develop and field test three years of problem-based mathematics that would satisfy the a-f University of California requirements for high school mathematics.

## Program Goals

The goals of the Interactive Mathematics Program (IMP) were to:

- broaden who learns mathematics, by making the learning of core mathematics accessible to groups previously under-represented in college mathematics classes;
- expand what mathematics was learned, consistent with the recommendations of the Curriculum and Evaluation Standards (NCTM, 1989), emphasizing problem solving and the communication of mathematical ideas;
- change mathematics instruction, by requiring students to be active learners and investigators, by integrating the study of mathematical domains, such as algebra, geometry and statistics, with each other and with areas of application, and by making use of current technology;
- change how teachers perceive their roles, by emphasizing the role of the teacher as guide and model learner and by changing dominant modes of classroom communication from teacher explanation to student interaction;
- change how mathematics learning is assessed, by assessing students' use of mathematical knowledge to solve complex problems, and by diversifying assessment strategies to include student portfolios, self-assessment, teacher observations, oral presentations, and group projects, as well as written homework and tests.

# **Pupil Selection**

Methods of selection of pupils for participation in the IMP classes varied. The principal criterion was student self-nomination. Selection methods varied across the three school sites. One high school collected information on student performance, instructional preferences and academic history, and then selected "60% of the group who would have been placed in Algebra and 40% from those below." It did not appear that the sample of IMP students arising from the various selection criteria were of higher academic standing than those students in conventional Algebra classes.

#### Teacher Selection

Teachers were also chosen by self-nomination.

## The IMP Materials

The IMP materials consist of modular units, each requiring approximately five weeks of instructional time. These units employ historical, literary, scientific and other contexts to provide a thematic coherence to the students' exploration of mathematics. For instance, in one unit the Edgar Allan Poe short story *The Pit and the Pendulum* is used to facilitate student investigation of variation, measurement uncertainty, normal distribution, graphing, mathematical modelling, and non-linear functions. The instructional sequence of each unit

addresses mathematical concepts and skills and mathematical problem solving in a context that provides both the rationale for the skills being acquired and a means of integrating newly acquired knowledge within a coherent structure.

#### An IMP Classroom

Class size averaged around 32. Classroom activities were typified by group work, writing, and oral presentations. Graphing calculators were available at all times. The characteristics of IMP and Algebra classrooms, as perceived by the pupils, were documented in the course of this study, and are detailed in the results which follow.

## Assessment Practices

Priority was given in IMP classrooms to a diversity of assessment strategies, consistent with the program goals. For example, in one IMP class, grades were calculated from student performance on homework (30%), classwork and class participation (30%), problems of the week (30%), and unit assessments (10%). It appeared that most assessing of Algebra students was through weekly quizzes and chapter tests.

## **METHOD**

# Subjects

The subjects of this study were 182 students at three Californian high schools participating in the IMP program outlined above. In addition, matching data were collected on 74 Algebra 2 students and 143 Algebra 4 students from the same schools. Data on a further 52 Algebra 2 students were collected from a fourth high school to provide a numerically comparable sample of students at the same level as the IMP pupils.

#### Procedures and Measures

During June, towards the end of the academic year, all students completed two questionnaires:

- a Mathematics Belief questionnaire examining student perceptions of their mathematical competence, and student beliefs about mathematical activity, the origins of mathematical ideas, valued activities which assist in learning mathematics, typical classroom activities in mathematics, and attitudes to mathematics;
- a Mathematics World questionnaire requiring students to identify the extent to which specific everyday activities were mathematical.

At the time of administration of the questionnaires, IMP students had completed almost one year in the program.

In addition, the next Fall the Mathematics Scholastic Aptitude Test (SAT) was administered to the school populations, facilitating comparison of the mathematics performance of IMP students with their peers in conventional classes.

Mathematics belief. The mathematics belief questionnaire was adapted from an instrument employed to measure the student belief outcomes of an innovative program employing student journals (Clarke, Stephens and Waywood, in press). Every item had been validated through interviews with students. Minor changes in phrasing were made for administration in American schools.

Mathematics world. The mathematics world questionnaire was adapted for American administration from an instrument employed in a study of community perceptions of mathematical activity (Clarke and Wallbridge, 1989; Wallbridge, in progress). In this questionnaire, students were asked to indicate whether they thought specific everyday activities were highly mathematical, quite mathematical, slightly mathematical, barely mathematical, or not mathematical.

#### RESULTS

The results which follow make reference to three groups of students:

- i) 180 IMP students mean age 15.3 years
- ii) 126 Algebra 2 students mean age 15.4 years
- iii) 137 Algebra 4 students mean age 16.9 years

## Comparing the Algebra 2 and Algebra 4 Samples

In all, 48 student measures were generated through the two questionnaires. Algebra 2 and Algebra 4 samples (n = 126 and n = 137, respectively) did not differ significantly on any of the 48 measures except the use of worksheets, for which the Algebra 4 students recorded an even lower incidence than did the Algebra 2 students, and the importance accorded to the teacher's explanations: Algebra 4 students attached lower importance to these than did the Algebra 2 students. It seems reasonable to summarise these findings by observing that, with respect to the beliefs documented here, conventionally-taught students adhere to a specific set of beliefs with a high level of stability over time. These beliefs and the associated perceptions of classroom practice were sufficiently coherent and distinct from those held by IMP students to suggest general belief characteristics of both class types. Results are given as comparisons between IMP and Algebra 2 students since these represent the most similar sample populations. However, the uniformity of view among the Algebra 2 and Algebra 4 samples from four Californian high schools suggests a homogeneity among the "conventionally taught" pupils that supports the representativeness of the Algebra 2 sample and encourages extrapolation of the findings of this study as they relate to text-oriented, conventionally-taught, US and Australian classrooms.

In each table where comparisons are made between groups the corresponding p-value is given. A complete listing of all questionnaire items and a more extensive discussion of findings can be found in Clarke, Wallbridge, and Fraser (1992).

# Student Mathematics Achievement on Conventional Tests

Where comparison was possible between IMP and Algebra 2 students at the same school, mean SAT scores for IMP classes were higher than mean SAT scores for traditional Algebra/Geometry classes. At one high school this difference in performance was statistically significant. These results are documented in Table 1.

Table 1: Comparison of mean SAT scores of Algebra and IMP students on two school sites

School	Class type	Mean SAT score	S.D.	p value
· A	Algebra	420.48	82.96	.0372
·	(n = 83)	442.27	77.01	
	$ \begin{array}{c} \text{IMP} \\ (n = 74) \end{array} $	443.37	77.21	* .
В	Algebra (n = 86)	367.56	57.02	.1003
	IMP (n = 67)	373.88	60.95	

# Student Perceptions of Their Mathematics Competence

IMP students were significantly more likely to rate themselves highly on how good they were at mathematics than were Algebra 2 students (Table 2).

## Sample Item:

If I had to give myself a score out of 10 to show, honestly, how good I think I am at math, the score I would give myself would be:

**Table 2:** Mean self-rating scores for IMP and Algebra 2 students

Class Type	Mean	S.D.	p value
Algebra 2	6.86	1.2	.0012
IMP	7.5	1.38	

Two comments should be made concerning this higher self-rating by IMP students. First, SAT scores indicated that where comparison was possible IMP students tended to be more capable at conventional mathematics tasks than were their peers in Algebra classes, which suggests that these self-ratings had some basis in fact. Second, the difference in self-ratings can also be interpreted as a difference in confidence. We would suggest that heightened self-confidence in mathematics is likely to lead to increased participation in further mathematics, and a greater likelihood that the student will make use of the mathematical skills acquired. Both are desirable outcomes.

# Student Attitude to Mathematics Classes

IMP students were significantly more likely to feel positive about mathematics classes (Table 3).

# Sample item:

How do you feel in math classes at the moment?

A. Interested

B. Relaxed

C. Worried

D. Successful

E. Confused

F. Clever

G. Happy

H. Bored

I. Rushed

J. (Write one of your own)

A student attitude index was calculated by scoring each positive response +1 and each negative response -1, and summing for each student.

**Table 3:** Mean student attitude index for IMP and Algebra 2 students

Class Type	Mean	S.D.	p value
Algebra 2	52	1.85	.0001
Algebra 2 IMP	.97	2.14	

# Student Perceptions of Mathematical Activity

The distinguishing characteristic between the problem solving students and the Algebra 2 students was the degree to which they perceived mathematics to be a mental activity (Table 4).

## Sample Item

Mathematics is something I do (circle one or more):

- A. Every day as a natural part of living
- B. Mostly at school
- C. With a pencil and paper
- D. Mostly in my head
- E. With numbers

**Table 4:** Student perceptions of mathematical activity (proportion of students selecting each alternative)

Response alternatives	Class type	Proportion (%)
Every day as a natural part of living	Algebra 2	49
	IMP	52
Mostly at school	Algebra 2	63
	IMP	. 64
With a pencil and paper	Algebra 2	41
	IMP	42
Mostly in my head	Algebra 2	27
	IMP	39
With numbers	Algebra 2	51
	IMP	46

Table 4 is significant in the context of this paper in that it was only in these perceptions of mathematical activity that the IMP and Algebra students responded in a similar fashion. The marked differences in beliefs and perceptions reported by the two groups, which constitute the essential findings of this study, are only evident in Table 4 in the greater inclination for IMP students to report mathematics as being a mental activity.

# Student Perceptions of Mathematical Ideas

IMP students were more likely to agree that mathematical ideas could be clearly explained using every day words that anyone could understand, than were Algebra 2 students. IMP students were also less likely to view the ideas of mathematics as ones that can only be explained using numbers and language specific to mathematics. The IMP students were more likely to view mathematics as having developed in response to people's needs. The IMP students were also less likely than the Algebra 2 students to view mathematics as having been invented by mathematicians or to hold that the ideas of mathematics have always and will always be true. Table 5 documents these differences.

## Sample Item

The ideas of mathematics

A. Have always been true and will always be true.	Agree	Disagree
B. Were invented by mathematicians	Agree	Disagree
C. Were discovered by mathematicians.	Agree	Disagree
D. Developed as people needed them in daily life.	Agree	Disagree
E. Have very little to do with the real world.	Agree	Disagree
F. Are most clearly explained using numbers.	Agree	Disagree
G. Can only be explained using mathematical language		,
and special terms.	Agree	Disagree
H. Can be explained in everyday words that anyone		
can understand.	Agree	Disagree

**Table 5:** Students' perceptions of the ideas of mathematics (Agree/Disagree responses were scored +1/-1, so mean scores represent the proportionate majority view.)

Sub-items	Class type	Mean
Have always been true and will always be true.	Algebra 2	.016
	IMP	28
Were invented by mathematicians.	Algebra 2	13
	IMP	36
Were discovered by mathematicians.	Algebra 2	.18
	IMP	.01
Developed as people needed then in daily life.	Algebra 2	.57
	IMP	.77
Have very little to do with the real world.	Algebra 2	72
	IMP	82
Are most clearly explained using numbers.	Algebra 2	.26
	IMP	02
Can only be explained using mathematical	Algebra 2	41
language and special terms.	IMP	69
Can be explained in everyday words that		.21
anyone can understand.	IMP	.63

In summary: IMP students were more likely to hold a socially-oriented view of the origins and character of mathematical ideas rather than a platonist belief in the existence of mathematical absolutes awaiting discovery.

# Student perceptions of School Mathematics

The IMP students were significantly more likely to agree that writing was important in helping them to understand mathematics. The IMP students were also more likely to see value in talking to other students than were the Algebra 2 students. The IMP students were significantly less likely than the Algebra 2 students to view drill and practice as the best way to learn mathematics.

## Sample Item:

Circle the alternative which best describes how true you think each statement is (SA = Strongly Agree, A = Agree, D = Disagree, and SD = Strongly Disagree):

•	Explaining ideas clearly is an important part of mathematics	SA	Α	D	SD
•	Mathematics does not require a person to use very many words	SA	Α	$\mathbf{D}$	SD
•	Writing is an important way for me to sort out my ideas				
	in mathematics	SA	Α	D	SD
•	Talking to other students about the mathematics we are doing				
	helps me to understand	SA	Α	D	SD
•	Drill and practice is the best way to learn mathematics	SA	Α	D	SD

The distinguishing characteristics between the IMP students and the Algebra 2 students were:

- the importance attached by IMP students to writing in mathematics (p = .04)
- the degree to which IMP students perceived talking to other students as useful in helping them to understand mathematics (p = .0005)
- the relative importance attached to drill and practice by the Algebra 2 students (p = .0001)

# Student Perceptions of Mathematical Activity at School

The greatest degree of difference between IMP students and the Algebra 2 students was evident in their perceptions of mathematical activity at school.

Table 6 illustrates the differences in student perceptions of their mathematics classrooms. In these figures, the differences between the two class types are most clearly illustrated. Key differences between IMP and Algebra 2 classes can be summarised as follows:

- IMP students were significantly more likely to be writing words and drawing diagrams, and less likely to be writing numbers.
- IMP students were significantly more likely to be working with a friend or with a group, and less likely to be working on their own.
- While there was no difference between IMP and Algebra 2 classes in the relative frequency of listening to the teacher, IMP students were significantly more likely to be listening to other students than were students in Algebra 2 classes.
- IMP students were significantly more likely to be working from a worksheet and less likely to be copying from the board or working from a textbook.

Students were asked to respond on a five-point scale to the cue "When doing mathematics at school, I am likely to be ..." The mean values in Table 6 should be read as students' perceptions of the relative frequency (on a 5-point scale) with which they engaged in each of the listed activities.

**Table 6:** Mean relative perceived frequency of student engagement in each activity (5-point scale).

Sub-items	Class type	Mean	S.D	p value
Talking	Algebra 2	2.25	1.0	.002
	ĬMP	2.59	.88	
Writing numbers	Algebra 2	3.13	.86	.0001
·	IMP	2.66	.83	
Writing words	Algebra 2	1.70	.93	.0001
	IMP	2.68	.94	·
Drawing diagrams	Algebra 2	1.85	.82	.0001
	IMP	2.70	.83	
Working on my own	Algebra 2	2.59	.90	.0001
	IMP	1.91	.87	
Working with a friend	Algebra 2	2.10	.90	.0001
	ĬMP	2.69	.80	
Working with a group	Algebra 2	1.96	1.0	.0001
	IMP	3.17	.80	·
Listening to the teacher	Algebra 2	2.80	.98	.63
	IMP	2.75	.96	
Listening to other students	Algebra 2	2.19	.96	.0001
	IMP	2.79	.83	
Copying from the board	Algebra 2	2.40	1.02	.0001
	IMP	1.91	1.04	
Working from a textbook	Algebra 2	3.15	.93	.0001
	IMP	0.25	.70	
Working from a worksheet.	Algebra 2	2.05	1.06	.0001
	ĬMP	3.32	.97	

# Student Perceptions of the Relative Importance of Course Components

IMP students valued working with others significantly more highly than did Algebra 2 students (p = .0001). By contrast, Algebra 2 students valued the teacher's explanations (p = .0005), and the textbook (p = .0001) more than did IMP students.

# Student Perceptions of Mathematics in Everyday Activity

IMP students were significantly more likely to identify a mathematical component in everyday activities than were Algebra 2 students. This result is evident in Table 7.

**Table 7:** Mean math world index for students in Algebra and IMP classes

Class type	Mean	S.D.	p value
Algebra 2 (n = 113)	19.292	5.591	.0014
IMP (n = 172)	21.477	5.598	

This greater willingness to recognize mathematical elements in everyday activities may be a consequence of the problem-based and context-specific nature of most of the IMP program.

### Gender differences

Comparison was made in this study of the attitudes to mathematics of boys and girls in IMP and Algebra classes, and of the boys' and girls' self-ratings of their mathematics competence. These results are shown in Table 8.

**Table 8:** Self-ratings and attitude measures for students in Algebra 2 and IMP classes: Comparison by gender.

Class type	Measure	Gender	Mean	S.D.	p value
Algebra 2	Self-rating	Male	7.333	1.875	.0101
		(n = 58)			
		Female	6.433	1.994	
]		(n = 67)			
IMP	Self-rating	Male	7.636	1.297	.081
		(n = 77)	7.071	1 410	
		Female	7.271	1.410	
A11 0	A selection	(n = 96)	0.245	1 001	2176
Algebra 2	Attitude	Male	-0.345	1.821	.3176
		(n = 58) Female	-0.676	1.872	
		(n = 68)	-0.070	1.072	
IMP	Attitude	Male	0.756	2.021	.2344
. 11411	Tittlado	(n = 78)	0.750	2.021	.25 11
		Female	1.146	2.234	
		(n = 96)			

Girls in both class types were less likely to rate their own mathematical competence highly than were boys. However this difference was only statistically significant for students in Algebra classes. Both boys and girls in IMP classes had similar positive attitudes to mathematics. In Algebra classes, both male and female students felt negatively towards mathematics, however boys' attitudes were less negative than those of girls. On the basis of these findings, it appears that the IMP program was of particular value to female students.

# **CONCLUSIONS**

The inclusion of the Algebra 4 sample in the study encourages the extrapolation of conclusions from comparisons of class types at a specific grade level to more general conclusions comparing problem-based and conventional instruction for high school mathematics classes. The conclusions which follow, however, relate specifically to the study sample.

# A. The students as learners.

- 1. IMP students rated themselves as significantly more mathematically able than did the Algebra students.
- 2. IMP students held a significantly more positive attitude towards their mathematics classes than did the Algebra students.
- 3. On school sites where comparison was possible, IMP students averaged higher SAT scores than did pupils of conventional classes.
- 4. IMP classes appeared to have less negative outcomes for girls than did conventional Algebra classes.

# B. Student perceptions of mathematics

- 5. IMP students were significantly more likely to perceive mathematics as a mental activity.
- 6. IMP students held beliefs consistent with a view of mathematics as arising from individual and societal need; while Algebra students were more likely to view mathematical ideas as having an independent, absolute and unvarying existence.
- 7. The IMP students were significantly more likely to perceive mathematics as having applications in daily use.
- 8. IMP students were significantly more likely than Algebra students to believe that mathematical ideas can be expressed "in everyday words that anyone can understand".

#### C. Instructional alternatives

- 9. IMP students attached significantly more value to interactive learning situations; whereas, Algebra students valued "the teacher's explanations" and "the textbook".
- 10. IMP students valued writing and talking to other students as assisting their learning. Algebra students were significantly more likely to value "drill and practice".
- 11a. It is possible to identify a coherent and consistent set of classroom practices which can be associated with conventional instruction (cf. Clarke, 1984). The relative frequency of particular classroom activities reported in Clarke (1984) is consistent with the emphases reported by students in Algebra classes in this study.
- 11b. IMP students' reports of the frequency of engagement in particular activities suggest a set of classroom practices which would identify, in the students' view, the characteristics of the IMP classroom.
- 11c. The characteristics of these two instructional models appear sufficiently distinct to represent clear alternatives.

In conclusion, the classroom practices of the IMP program, as reported by the students, placed greater emphasis on a variety of modes of communication and on facilitating student-student interaction than was the case with conventional instruction. By contrast, conventional instruction was perceived as solitary, text-driven, and typically expressed through special terms and numbers.

To what aspect of the IMP experience might we attribute the student beliefs documented in this study? The small-group, interactive classroom and the problem-based mathematics curriculum represent two key characteristics of the Interactive Mathematics Project. Whether such belief systems would arise in interactive classrooms lacking a problem-based emphasis or in more conventionally-taught problem-based classrooms is a matter for further research.

With respect to mathematics achievement outcomes, IMP students were at least as successful as their conventionally-taught peers on conventional tasks, as represented by the SAT. Performance on non-routine tasks will be investigated in a later study.

Certainly the IMP program has provided students with significantly different experiences from those found in conventional mathematics classes, and these experiences appear to have led to demonstrably different beliefs about mathematical activity, mathematics learning, school mathematics, and the mathematics evident in everyday activity.

This research suggests that a problem-based curriculum is capable of developing traditional mathematical skills at least as successfully as conventional instruction, while simultaneously engendering measurably different belief systems in participating students.

#### **ACKNOWLEDGEMENTS**

The cooperation of the teachers whose pupils participated in this study is gratefully acknowledged. The comments of Barry McCrae, Kevin Olssen, Diane Resek, and Peter Sullivan on early drafts of this paper are also gratefully acknowledged.
